

Problem 4.9

The important thing to consider is the following

This would be a difficult piecewise integral so, we use $1 - P(X - Y > z)$

For $z > 0$,

$$\begin{aligned} P(X - Y < z) &= 1 - P(X - Y > z) \\ &= 1 - \iint_{\substack{0 \\ z > y}}^{\infty \infty} f_{X,Y}(x,y) dx dy \end{aligned}$$

For $z < 0$,

$$\begin{aligned} P(X - Y < z) &= \iint_{\substack{0 \\ z < y}}^{\infty \infty} f_{X,Y}(x,y) dy dx \end{aligned}$$

Notice, this is different.

If you solve these integrals, you will get the CDFs you need.

Problem 4.17

In the statement that we can assume \bar{X} and \bar{Y} have zero mean, they mean to say that because

$$\text{cov}(\bar{X}-\bar{Y}, \bar{X}+\bar{Y}) = \text{cov}(\bar{X}-\bar{Y}+b, \bar{X}+\bar{Y}+c) \text{ where } b \text{ and } c \text{ are scalars.}$$

then we can simplify our math by assuming that $E[\bar{X}] = 0$, $E[\bar{Y}] = 0$

$$\begin{aligned} \text{cov}(\bar{X}-\bar{Y}, \bar{X}+\bar{Y}) &= E[(\bar{X}-\bar{Y})(\bar{X}+\bar{Y})] - E[\bar{X}-\bar{Y}] E[\bar{X}+\bar{Y}] \\ &= E[(\bar{X}-\bar{Y})(\bar{X}+\bar{Y})] - \underbrace{(E[\bar{X}]-E[\bar{Y}])(E[\bar{X}]+E[\bar{Y}])}_{\text{This can then be eliminated}} \\ &= E[(\bar{X}-\bar{Y})(\bar{X}+\bar{Y})] \\ &= E[\bar{X}^2] - E[\bar{Y}^2] \\ \text{Because } E[\bar{X}] = 0 \text{ and } E[\bar{Y}] = 0 \\ &= \text{var}(\bar{X}) - \text{var}(\bar{Y}) \\ &= 0 \text{ because } \text{var}(\bar{X}) = \text{var}(\bar{Y}) \text{ by assumption.} \end{aligned}$$
